

# Darwin Plus: Overseas Territories Environment and Climate Fund Annual Report

**Important note** To be completed with reference to the Reporting Guidance Notes for Project Leaders: it is expected that this report will be about 10 pages in length, excluding annexes

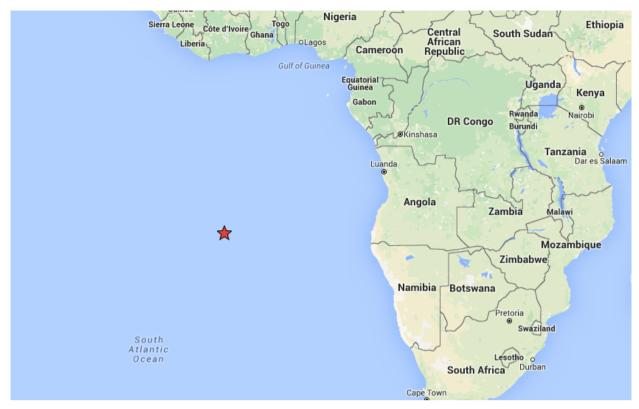

Submission Deadline: 30<sup>th</sup> April 2017

# **Darwin Plus Project Information**

Project reference	DPLUS037
Project title	Conserving the genetic diversity of St Helena's threatened endemic flora
Territory(ies)	St Helena
Contract holder institution	Royal Botanic Gardens, Kew
Partner institutions	St Helena Environmental Management Division (St Helena Government)
Grant value	£69,247 (£7,910 2016/17)
Start/end date of project	1 April 2015 – 31 September 2017 (six month no cost extension to the project approved by Darwin)
Reporting period (e.g., Apr 2016-Mar 2017) and number (e.g., AR 1,2)	April 2016 – March 2017 AR2
Project leader name	Thomas Heller
Project website/blog/Twitter	https://storify.com/KewUKOTs/conserving-the-genetic-diversity-of-st-helena-s-th
Report author(s) and date	Thomas Heller, Marcella Corcoran, Vanessa Thomas-Williams

# 1. Project overview

This project is focussed on the conservation of the threatened endemic flora of St Helena in the South Atlantic Ocean, an isolated island more than 1000 miles from the coasts of Angola and Namibia.

St Helena is home to 45 endemic higher plant species, many under severe threat of extinction, with at least ten with fewer than 100 plants remaining in the wild, and several more with fragmented, small or declining ranges. *Ex-situ* material (banked seeds, plants in cultivation) are an important resource for conservation activities in St Helena, being used as a source of plants for habitat restoration and species reintroductions, as well as providing long term security for genetic diversity where the outlook for individual wild populations is uncertain. This project is seeking to improve the representation of the threatened endemics in *ex-situ* collections through a gap analysis of existing *ex-situ* collections, capacity building in seed conservation and horticulture (training and equipment), and collecting and banking seeds and spores of endemic plants.

# 2. Project stakeholders/partners

The Environmental Management Division of the St Helena Government has responsibility for effective management of the environment on the island, including its plant life, and is therefore the principal stakeholder and partner in this project. Much of the capacity building and activities are focussed on the teams working within EMD. The project proposal was developed in direct collaboration between Kew and EMD from the outset.

The principal activities for this second year of the project have been developing ex-situ collections of St Helena's endemics (Activities 3.1-3.5), as well as surveying inaccessible localities by quadcopter drone (Activity 1.3). Largely due to the relative unpredictability of the timing of plants setting fruit, but also St Helena's isolation and consequent expense of travel from the UK, this activity is one that is undertaken solely by in-country staff of the EMD this year. With extensive experience of working with the endemic plants in the field, along with data mobilised through the gap analysis (Output 1, https://goo.gl/T4RY7a), EMD staff are well placed to undertake monitoring and day-to-day decisions on targeting plants for seed collecting. Nevertheless, Kew staff have been available to respond to any technical gueries and provide advice where required, such as handling fern spores. The main challenge in this regard is that any issues affecting team members has an impact on activities that is not easily mitigated. For example, a persistent foot problem experienced by Vanessa Thomas-Williams, requiring surgery, has severely limited her ability to undertake field work on the difficult terrain of the island. While her team are able to continue visits to the field, deployment of the drone is not easily delegated, as only Vanessa has the training and experience of using the quadcopter to date.

During Year 1 of the project, staff of the St Helena National Trust and the Landscape and Ecology Mitigation Programme participated in the in-country horticultural training delivered by Marcella Corcoran (RBG Kew). Horticultural support from Kew has continued in Year 2 of the project, with Marcella available to respond to requests for advice on managing horticultural *exsitu* collections of endemic plants from SHNT and LEMP nursery staff.

## 3. Project Progress

#### 3.1 Progress in carrying out project Activities

Activities 1.1 (compiling data), 1.2 (gap analysis and collecting targets), 2.1 (UK training for St Helena-based staff), 2.2 (in-country training for St Helena-based staff), 2.3 (procuring equipment) were all completed in Year 1 of the project and were reported in AR1.

Activities planned for this year of the project were 1.3 (surveying sites by quadcopter drone) and continuation of Activities 3.1 to 3.5 (monitoring target populations, making, processing, banking and shipping seed collections).

Activity 1.3 Key populations and remote locations surveyed by drone. Time has been spent by Environmental Management Division (EMD) staff gaining flying experience with the quadcopter drone. Two challenges have limited implementing this activity: the mobility of a key team-member (see section 2, above); and suitable weather conditions, with exceptionally still conditions required for flying in the typically exposed sites of particular interest, where the prevailing wind speeds are close to the limit recommended for flying the quadcopter. Sites for surveying have been identified for survey in the coming months. See Annex 3.

Activity 3.1 Monitor target populations for availability of seed, & 3.2 make seed collections Members of the Environmental Management Division (EMD) team have been making regular visits to target populations across the island identified in the gap analysis and, while success has been met in locating target populations, few plants have been found to be in fruit. Rainfall over the last year has been unusually dry, with data from the Bottom Woods meteorological station indicating that rainfall for the 2016 calendar year was as much as 30% below the mean rainfall for the past 40 years, with only 1984 recorded as being drier. August 2016 was the driest recorded, 70% below the mean for this month. See St Helena Government announcements regarding the drought <a href="https://goo.gl/BLWKeu">https://goo.gl/jizhBs</a>, and copy of rainfall data supplied from Bottom Woods meteorological station <a href="https://goo.gl/hqvBFq">https://goo.gl/hqvBFq</a>. This lack of rain has had a marked impact on the flowering and fruiting of St Helena's endemic plants, with very few species yielding sufficient quantities of seeds for collecting. 11 collections have, though, been possible. These are (see also Annex 4):

Berula bracteata from behind High Peak, a species only represented by a single collection at the MSB from a different locality, and not banked before in-country.

Commidendrum robustum from Thompson's Wood Campground, one of the populations highlighted for targeting in the project gap analysis as not being duplicated at the MSB.

Carex dianae collections from Longwood Barn and High Peak Dell, both of which are populations identified for targeting in the gap analysis.

Petrobium arboreum collections from High Peak and High Ridge, a species not previously banked at the MSB.

*Pladaroxylon leucadendron* collections from High Peak and Diana's Peak, a species not previously banked at the MSB.

Osteospermum sanctae-helenae from EMD's native plant nursery. Though cultivated, the provenance of these plants is a population now extirpated by the airport development.

Frankenia portulacifolia from Man and Horse Cliffs. Though not a target population, it is a significant collection in terms of quantity from a species which typically produces small numbers of seeds.

Commidendrum spurium from Mount Vesey, the only remaining wild population, and a significant addition to the *ex-situ* collections of this species.

Herbarium vouchers have not been collected, due to the small and vulnerable nature of the populations concerned. However, the experience of EMD staff working with all the endemic species gives confidence in their correct identification. Leaf samples collected in silica gel provide us with options for better understanding of the diversity and historical introgression of St Helena's endemics.

Activity 3.3 Dry and clean seed collections, & 3.4 bank seed collections locally All collections have been dried using a silica gel drum-dryer, and cleaned, using a combination of hand-sorting, sieving, and Agriculex aspirator, where appropriate, and moisture levels monitored using a TinyTag hygrometer probe. See Annex 3.

Activity 3.5 Ship duplicate seed collections to the Millennium Seed Bank Three of the seed collections made this year have been sent to the MSB. See Annex 5. A further batch of seed collections will be sent for duplication at the MSB in May with a resident travelling to the UK, with 8 collections made during the reporting period, as well as collections made during April 2017 (an additional 12 collections so far. These will be reported in the final project report). A final batch of material will be sent to the UK in the final month of the project.

# 3.2 Progress towards project Outputs

#### Output 1 Gap analysis and action plan

Aspects of this output relating to consolidating disparate data sources and undertaking a gap analysis were completed in Year 1 and evidence provided in AR1. See logframe presented in Annex 2. There are no further developments to report here, as planned.

Many localities on St Helena are challenging to access due to the difficult terrain, and are home to poorly-known, or indeed likely hitherto undiscovered populations of endemics. The use of a radio-controlled quadcopter is one solution to survey such areas, and a DJI Phantom drone was purchased for this purpose, and some training was provided to EMD staff in Year 1 (see AR1). A number of challenges has prevented deployment of the drone to the level intended at the outset, as explained in Section 3.1, above. The information gained through surveying using the drone will be used as an indicator of success of this aspect of Output 1 in the final report.

# Output 2 Capacity building: seed conservation and horticulture skills and equipment

Again, the activities relating to this Output were completed in Year 1 of the project, and reported in AR1.

# Output 3 Ex-situ collections

The development of *ex-situ* seed collections has been the main output planned for this year, with the number of endemic plant species with at least one new collection banked used as an indicator of success in delivering this output. For the project to date, new collections of 21 of the 45 endemic plants have been made (16 seed plants, and 5 species of ferns, see <a href="https://goo.gl/73yHO5">https://goo.gl/73yHO5</a> for a list of endemic species and the numbers of collections made of each). Progress towards delivering this output has been severely set back by the drought experienced by St Helena over the past year, as explained in section 3.1, above. 22 species remain to be collected in the next six months. 2 species are not likely to be banked during this project: *Lachanodes arborea*, for which initial work suggest that its seeds do not survive drying (see Annex 3), and *Hymenophyllum capillaceum*, which has green spores and therefore not a good candidate for banking using conventional seed-banking protocols.

A further indicator of success towards this output is the size of collections made, with 500 seeds as a target. This indicator is a useful measure of success (larger collections permit greater use, such as in germination testing, research and propagation), though accurate seed counts are not easily achieved in-country, and the time-lag between receipt of collections at the MSB and availability of seed counts is rather long to enable full reporting during the lifetime of the project. 19 collections received at the MSB have been processed to date, data from which is presented (see <a href="https://goo.gl/pAEW8T">https://goo.gl/pAEW8T</a>). 14 of these collections are of more than 500 seeds

or spores (after taking into account that collections are split approximately 50/50 between EMD's collections and the MSB). Due to the minute size of fern spores, the MSB is only able to estimate numbers (as they do with orchid seeds). All fern collections have been estimated as consisting of more than 5000 spores. 5 collections fall below the threshold of 500 seeds, as a result of limited availability in the field, and are flagged for 'bulking up' through propagation of nursery plants. It is anticipated that figures will be available for all the collections made thus far in the project, but not those collected in the final months.

The genera known or suspected of hybridisation amongst the species in St Helena are *Trochetiopsis, Commidendrum, Berula* and *Wahlenbergia*. The collections of the first two genera have been from plants considered sufficiently isolated to preclude the possibility of hybrid progeny. The collection of *Berula bracteata* was made from a population where cross pollination with *B. burchellii* is a possibility, but unconfirmed. Collections of *Wahlenbergia* have yet to be made for this project. See Annex 4, and gap analysis (<a href="https://goo.gl/Jvx4YH">https://goo.gl/Jvx4YH</a>).

# 3.3 Progress towards the project Outcome

"Output 1 will ensure that collecting is done in a targeted manner and thus new ex-situ collections will be a valuable addition to those already existing, capturing a greater range of threatened genetic diversity". As previously noted (see AR1), the gap analysis is proving to be a useful exercise in directing collecting efforts for this project. Combining data from recent comprehensive field surveys with known ex-situ collections has been revealing. While it was known at the beginning of the project that EMD had amassed significant numbers of seed collections in their local seed bank, (of cultivated and wild origin), with very good coverage of the most well-known and largest populations, the gap analysis shows that for many of the endemics, a number of sites have not previously been sampled (see gap analysis <a href="https://goo.gl/Jvx4YH">https://goo.gl/Jvx4YH</a>). These gaps should be high priorities for targeted collecting because, although few of the species have been the subject of genetic analysis, there is a strong likelihood that these isolated populations harbour genetic variation not present in 'core' populations. These gaps have continued to be addressed through collecting for this project. Most of the collections made this year have been from target populations (see Activity 3.1 in section 3.1, above.

As explained in Sections 3.1 and 3.2 above, full deployment of the drone has been limited, but it is anticipated that the final months of the project will see the drone used to survey some of the key sites identified, as EMD staff gain more confidence in flying the drone.

"Output 2 will ensure that conservation activities are carried out according to best practice during the lifetime of the project as well as building capacity for future conservation efforts".

Partners have given feedback attesting to the usefulness of the training give (in the UK and in St Helena, covering topics relating to horticulture and seed conservation), with some examples of highlights and some examples of resulting improvements (see Annex 3) and a report on horticultural activities at <a href="https://goo.gl/zg4OT1">https://goo.gl/zg4OT1</a>.

With regard to horticultural capacity building, of particular note is the benefits gained by relatively new members of staff with comparatively little horticultural experience. Techniques deployed as a consequence have included trialling different mixtures of growing media, which have produced often dramatic differences in vigour; and the importance of structured monitoring and recording data, giving a basis on which to measure progress and improvements.

With regard to seed conservation, feedback has highlighted the value of being able to monitor seed moisture relations using a hygrometer and techniques to better manage drying collections. Partners have also provided evidence (Annex 3) of making good use of the supplied equipment, including the aspirator, used to separate seed material from debris, and the oven, used to recharge silica gel used to dry the seeds.

"Output 3 will ensure that the genetic diversity of St Helena's threatened flora is conserved for future generations and available for use in plant reintroductions, habitat restoration and research".

As detailed in section 3.2, this is the outcome that has proven most difficult to make progress on during the past year, as a result of poor rainfall affecting the availability of seeds in wild plants. Nevertheless some significant *ex-situ* collections have been secured and now available for future conservation work, with the gap analysis providing a valuable baseline against which to measure success, with all collections filling an identified priority. Of particular interest are the spore collections made from endemic ferns, which have received little attention in *ex-situ* efforts in St Helena to date. These spores will form the basis of developing horticultural collections at Kew, and have highlighted the need for building capacity for culturing spores in-country, as has been achieved with success with ferns endemic to Ascension Island.

Nevertheless, much work remains to be done to achieve all that was planned to fully achieve this outcome. 22 species remain to be collected in the six months remaining of the project. Since late January, significant rainfall has resumed on St Helena, with the vegetation responding with new growth and flowering (see Annex 3). Indeed 12 collections have been made in April so far, including of 4 of the remaining 22 target species. Prospects of fully delivering Output 3 are good, though more work needs to be done to focus collecting on the more obscure populations described above, which will contribute more to the stated outcome, as these continue to be entirely absent from *ex-situ* accessions.

#### 3.4 Project support to environmental and/or climate outcomes in the UKOTs

St Helena's National Environmental Management Plan 2012-2022 outlines 10 headline objectives. This project contributes directly to two of these:

- "B. Enhance implementation of the NEMP through participatory planning, knowledge management and capacity building.": Use of the gap analysis is continuing to be of value in knowledge management and help identify priorities for conservation work. This project has included a significant element of capacity building through training.
- "D. Safeguard St. Helena's environment, both terrestrial and marine, for future generations through effective environmental management including through improving the status of biodiversity by safeguarding ecosystems, species and genetic diversity.": Not only do banking seeds in long-term facilities safeguard remaining genetic diversity, the material is of vital importance in the success of propagation, species reintroductions and habitat restorations all of which are part of safeguarding St Helena's environment.

The project is also contributing to commitments of the CBD, <u>Art.9</u> especially (*Ex-situ* conservation), but also <u>Art.12</u> (Research and training), <u>15</u> (Access to genetic resources), <u>17</u> (Exchange of information) and <u>18</u> (Technical and scientific cooperation); and directly to targets 8 ("At least 75 per cent of threatened plant species in ex situ collections…"), and 15 ("The number of trained people working with appropriate facilities sufficient according to national needs") of the <u>GSPC</u> and <u>Aichi target 12</u> ("By 2020 the extinction of known threatened species has been prevented…").

#### 3.5 Monitoring of assumptions

Three principal risks were identified at the design stage of this project:

- "Unusual seasonal weather results in poor seed production." This risk has come to bear in this past year, with exceptionally dry weather until late January (see Activity 3.1 in Section 3.1, above). The consequent poor availability of seeds resulted in the need to request a six month extension to the project, which has been granted.
- "Quadcopter is damaged or lost in inaccessible location." This risk still holds true. Indeed, with gusting winds, caution against flying in difficult conditions has been exercised by partners. Additional practice will hopefully give the confidence needed to fly the drone in more challenging conditions.
- "Injury due to difficult terrain." The original assessment of this risk is unchanged. That a number of target populations are in sites hard to access means that this risk remains a very important one to manage carefully. To access some populations is impossible with the

resources available to this project, while others may be accessible, but require careful assessment and planning.

# 4. Monitoring and evaluation

The first activity of this project to be completed was the data consolidation and gap analysis undertaken for Output 1. These provide a key baseline by which the ongoing collecting (Output 3) can be monitored, by the extent to which new collections fit the priorities identified. By comparing the range of seed collections banked by the end of the project with what existed at the outset we will have a good means of demonstrating an improvement in the range of material secured for future conservation work, an important outcome for this project. As already reported in previous sections, collections made to date compare favourably with targets identified in the gap analysis.

Partner feedback and reporting has given some indication of the effectiveness of the capacity building provided in year 1 (e.g Annex 3), though more detailed evidence of change would help to better demonstrate success in achieving the desired outcome. In view of this, a more structured questionnaire will be devised to aid partners in expressing improvements in methods and successes, such as ease of using new equipment, and information on seedling mortality.

#### 5. Lessons learnt

One of the main pitfalls of the project design during this last year has been the extent to which the remaining activities are only undertaken by staff EMD in St Helena. While at Kew we are in regular contact to provide technical support remotely, there is little that can be done assist directly with practical activities. It would have been better, though expensive, to have had further visits to St Helena by Kew staff. Though this would not have helped especially with collecting activities, given the drought, assistance in deploying the drone and horticultural support may have been of benefit to delivering the outputs.

# 6. Actions taken in response to previous reviews (if applicable)

Queries raised in the review of AR1, are addressed here:

"Are there any contingency plans if the drone is damaged during flying?": Spare rotors and rotor guards were purchased with the drone, as these are the parts most commonly damaged. Other spare parts and repairs are available in the UK if required, but may take some time due to the isolation of St Helena.

"Might drones be used to sample inaccessible plants?": Certainly drones available currently aren't capable of this. It is conceivable that drones could be modified to do this to some extent, but the variation in how seeds are presented in different species require dexterity and skill in order to not damage plants excessively.

Following Darwin guidance, the underspend in Year 1 was not available for use in year 2.

## 7. Other comments on progress not covered elsewhere

N/A

#### 8. Sustainability and legacy

The project has been designed to have a sustained legacy. The exercise to bring together various data sources and produce a gap analysis will help our partners with planning conservation activities beyond the lifetime of the project. Likewise, the capacity building (training and equipment) enabled by this project will improve the management of seed and horticultural collections, improving seed viability and longevity, as well as the success and efficiency of propagation work. The resulting improvement in *ex-situ* collections themselves is intended to have a long-term legacy, in that it is specifically intended to prevent further loss of

genetic diversity from what remains of the endemic plant species, diversity which is key to their long-term survival.

# 9. Darwin identity

Due to the drought limiting collecting activities, it has been difficult to gather interesting results and stories to promote the project. With collecting activities resuming at an increased pace, and planned use of the drone, there will be more opportunities to assemble materials to promote the project and activities through social media and other outlets (EMD newsletter, local news, Kew blog).

# 10. Project Expenditure

3.3 Species where hybridisation likely collected under controlled conditions.		

Activities (each activity is numbered according to the output that it will contribute towards, for example 1.1, 1.2 and 1.3 are contributing to Output 1)

- 1.1 Data sources from Kew and St Helena assembled, standardised and compiled.
- 1.2 Priority lists and collecting plans drawn up for all endemic species.
- 1.3 Key populations and remote locations surveyed by drone.
- 2.1 Staff from St Helena to visit Wakehurst Place for seed conservation and horticultural training.
- 2.2 Staff from Kew to visit St Helena to deliver in-country training and collecting and horticultural support.
- 2.3 Procure equipment and ship to St Helena.
- 3.1 Monitor target populations for availability of seed.
- 3.2 Make seed collections, with associated data and voucher specimens (either herbarium specimens or photos, as appropriate to vulnerability of target populations).
- 3.3 Dry and clean seed collections, using internationally approved protocols.
- 3.4 Seal and bank seed collections in local seed bank.
- 3.5 Ship duplicate seed collections to MSB.

# Annex 3 - supplementary material

# Report for DPLUS037 April 25<sup>th</sup> 2017.

# Problem Specie Lachanodes arborea

We been monitoring the *Lachanodes arborea* (she cabbage) for many years. This specie now extinct in the wild, but we been propagating this specie by seed and cutting now growing in cultivation. Some times in a flowering season we can collect 100 to 1000 seed and other times no seed. However only few trees been producing viable seed.

Unfortunately, we can't store the seed as other Asteraceae species like *Melanodendron integrifolium* and *Petrobium arboreum* all grown in the same habitat. We used the same seed processing techniques as other species. I hope we can get help from Kew and MSB for this specie.

We did an experiment, stored the seed for six months and a year, out of 100 seed, no seed germinated. We also try leaving the seeds for three days in the drying room and then sow the seed, no seed germinated. To get a good result we germinate the seed as soon as we collect them from fresh, normally a day, germination rate is 100%.

Over the years last two years the trees been flowering, many flowers but the seeds are not viable.

## Seed collecting in the wild

After the long dry period, St Helena started having rain since late January 2017 through February 2017 over this period of having rain the dryland annuals species started to germinate, this including Osteospermum sanctae-helenae, Hypertelis acida, Chenopodium helenense, Hydrodea cryptantha also the barn fern Ceterach haughtonii. Although we been collecting some of these species in cultivation from our living gene bank some of the plant populations are remote related species.

St Helena have seen climate change over the years which effected flowering seasons to all our endemic species, species flower and produce seed different times of the year. Most times we will start monitoring seed in the wild, timing the seed when it will be ready, only to get their mice and other invasive species already eaten the seed.

Also since the rain other endemic perennial species are starting to flower. The gap analysis has been useful in planning collection although some areas will be unsafe to get to.

20 collections will be sent to bank in the MSB and will be transport to Kew in May 2017, these species included two collections of *Petrobium arboreum*, two collections of *Pladaroxylon leucadendron*, and one collection of *Commidendrum spurium*, which were collected through the cloud forest project one collection of *Osteospermum sancate-helenae* grown in the living gene bank to help to increase seed production, this is the provenance of Dry gut Longwood (airport site). Two collections of *Frankenia portulacifolia*, one collection we don't have in our seed bank and MSB. We also mansion to collect a good sample of *Commidendrum rugosum* and *Eragrostis saxatilis* for the first time from Man and Horse cliffs. 8 species of fern collection were also collected. Also one collection from *Panicum joshuae*.

We will continue to monitor the areas highlighted in our gap analysis throughout the coming months. Below is two table showing weather details throughout the Island for the month of January and February 2017.

Man and Horse collecting Hair grass and scrubwood seed, also monitoring the tea plant.  $6^{\rm th}$  April 2017

Tea plants growing on cliffs next to sea shore. Manti bay, no seed. 19<sup>th</sup>

# Seed cleaning and equipment.

With the help from this project our section had the opportunity to received equipment to help with seed cleaning, a hygrometer to measure seed eRH. Also an oven which we used to dry out silica gel, for the drying bins.

Cleaning *Eragrostis episcopulus* seed and drying out silica gel.

Hand sorting seed collections

We have identify an area that we would like to send the drone to take some pictures in the next few months, hoping that the weather is right. We would like to see if we can spot any living extinct *Trochetiopsis melanoxylon*.

A training picture taken with the drone.

Training seed conservation and horticulture.

Horticulture training were good as we had new staff, this give them the opportunity to learn new

techniques.

Marcella did two weeks training in horticulture this included:

- RBG Kew ex-situ collections; St Helena priority species.
- Planning and setting up seed germination in trays and pots.
- Planning and setting up trials for vegetative prop by cuttings.
- Fern propagation vegetative of ferns. Collecting spores.
- Review of nursery facilities as a group. Threats to plants in the nursery.
- Practical-seed treatments and sowing.
- Cleaning spores/sow on compost. Transferring sporophytes to compost.
- Composting: what is possible? Growing media. Plant containers. Prep of seed for sowing.
- Watering and care of seed pots.
- Pricking out seedling and potting on plants.

- Recording germination and observation notes.
- Recording cultivation and monitoring successes.

September 2015 I had the opportunity to undertake overseas training in seed conservation techniques course, supported by this project.

The course was held at the Millennium seed bank, Wakehurst Place, whom we work closely with to safeguard our wild endemic plant diversity.

During the course we study theoretical aspects to seed banking such as seed-air moisture relations, seed storage behaviour, germination and dormancy

<u>Collecting spores from Elaphoglossum dimorphum (Toothed tongue fern) from the Depot.</u>

#### Dear Tom

Please see attached seed information, also the report we did on the Horticulture training. Karen and Stefan did the horticulture training they both say they enjoy the course, sowing seeds and propagation by cutting they say that it was the highlight because they sow seed in different compost and find out how the endemic germinate and develop in different compost, what compost to use for different species. It also give them the opportunity to know how importance monitoring, data collection is, and the results could help in the long term as reference.

My highlight of the conservation training knowing about the humidity in seed and how seed gain or lose moisture depending on the RH of the surrounding air. Because we don't have a drying room (nice to have one..) which is kept at one temperature. Here on St Helena we don't have a drying room, It was nice to know to cover the seeds at night, until we get the chance to sort the seed. Also at night seed take up moisture, which I didn't know, I really enjoy the whole course.

Take care

Kind regards

Vanessa
